

# 55NT PROCESSING GUIDELINES

## **55NT – HIGH TEMPERATURE EPOXY ON AN ARAMID FIBER REINFORCEMENT**

Arlon's 55NT combines the high temperature performance and thermal stability of a multifunctional epoxy on nonwoven aramid reinforcement. 55NT is engineered using this customized substrate for maximum control of CTE for SMT applications.

### **55NT PREPREGS**

55NT is designed at a nominal resin content of 49% to provide a CTE value in-plane of 7-9 ppm/°C as unclad material. Final CTE will depend on board and construction, copper content. The low resin content of 55NT will affect resin flow and applications requiring via hole fill may require higher resin contents or combined with the glass reinforced prepreg.

55NT prepreg as supplied has a nominal resin flow of 8% (IPC TM-650 2.3.17). The degree of chemical advancement of this resin is equivalent to that of a 1080 glass with a nominal 35% flow -the restriction in physical flow is due to the nonwoven character of the reinforcement.

The permeability of the nonwoven aramid fabric and the random orientation of the reinforcement act as a flow restrictor allowing the resin to be retained while encapsulating inner layer details. This results in improved thickness uniformity across the panel and more precision in the manufacture of controlled impedance boards.

### **55NT LAMINATE PRODUCTS**

Non-woven laminates are produced with Arlon's 55N multifunctional epoxy resin, identical to that supplied in prepreg to ensure total compatibility in bonding layers. The unique combination of aramid reinforcement with a high performance epoxy resin allows the material to be used as an economical replacement for other more costly methods of producing high density, high performance CTE controlled packages.

For additional technical information on 55NT laminate and prepreg including nominal prepreg pressed thicknesses for the various grades and resin contents, see the technical data sheet available at [www.arlonemd.com](http://www.arlonemd.com).

## **PROCESSING RECOMMENDATIONS**

### **CONTROL MOISTURE AT ALL CRITICAL STEPS**

Aramid reinforcements are sensitive to humidity and moisture. Water may be absorbed as a result of uncontrolled storage conditions as well as wet processing operations. Moisture must be removed prior to the multilayer lamination process as well as subsequent thermal excursions of plasma etch, solder reflow, wave soldering, hot air leveling, solder mask baking or thermal stress testing. If moisture is not removed, multilayer boards may exhibit delamination or blistering, and electrical performance properties may deteriorate. The most critical step is removal of moisture from laminates and prepregs prior to lamination.

### **PREPREG STORAGE CONDITIONS**

55NT is supplied in vapor barrier vacuum bags to minimize additional exposure to atmospheric humidity during shipment and storage. Once original factory supplied bags are opened, a vacuum desiccation cycle of 8 to 12 hours at 29+ inches of vacuum is recommended for preparation of prepreg for lamination. When mineral desiccants are used care must be taken to keep them refreshed and dry as aramid materials may “compete” with the desiccant for available moisture.

### **INNER-LAYER PROCESSING**

As received laminates do not require prebaking prior to Imaging as Tgs are fully developed and do not require stress relief. Conventional copper cleaning operations prior to dryfilm are acceptable, though care is needed during mechanical scrubbing to ensure the copper is not distorted which could change dimensional stability, CTE properties or induce warpage.

55NT are compatible with conventional alkaline and cupric chloride etching chemistries as well as aqueous resist strippers. Aramid fiber composites will absorb moisture more readily than e-glass materials, so laminates (as also true of prepregs) need to be thoroughly dried prior to lamination.

Inner layers processed with brown oxides provide good adhesion to 55NT prepregs. Other oxide alternatives have also provided acceptable results.

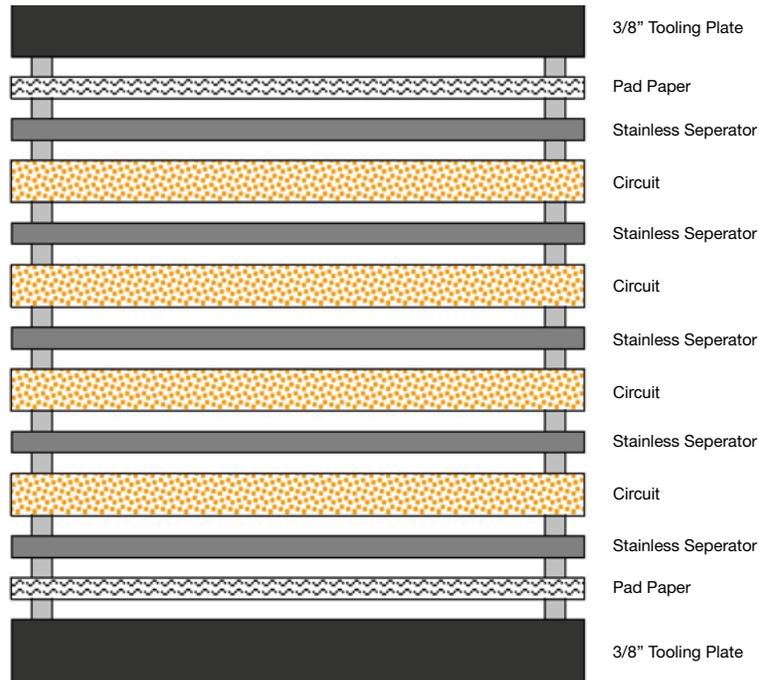

### **ARTWORK COMPENSATION**

Some adjustment may be required depending on the size and direction, residual copper circuit density, and tooling scheme used. This is the shrinkage that is expected after lamination. Growth is commonly seen in individual inner layer details after etch due to the release of the stress caused by the copper and core CTE mismatch and to any moisture absorption by the exposed layers. For 55NT, because the in-plane movement is less due both to the nature of the aramid substrate and the lower resin content, it is recommended that test layers be made using no more than

0.3 mils/inch compensation to establish dimensional change. Once comp factors are established for a given job, the material has proved very repeatable.

These values are based on using 3/8 inch tooling plates, 0.050 of press pad between the tooling and the first separator plate, and using 60 to 70 mil stainless separators. Use of aluminum or release films in the package may result in inconsistent material movement.

The following is the recommended book stack up for the press:

## LAMINATION

Layup should be completed as soon as possible (within 2 hours) after drying laminate (1 hours at 250°F followed by a 90 minute stabilization under desiccation), and desiccation of prepreg under vacuum (29+ inches of vacuum for 8-12 hours) for moisture removal. Try to keep lay-up operations within a two hour time period after removing materials from vacuum or desiccation steps. Use of parallel layup lines has been utilized in some cases to minimize exposure time. Keep exposed prepreg and laminate surfaces to a minimum to reduce moisture regain.

Nonwoven aramid is more compressible and porous than E-glass, so the resin flow to lamination pressure relationship is different. Slightly higher lamination pressures might be required compared to E-glass configurations. The heating rate should be controlled to a 4.5°C to 6.5°C/minute (8°F to 12°F/minute) heat rise between 100°C to 150°C (210°F and 300°F).

## SUMMARY OF LAMINATION RECOMMENDATIONS

- Heat Up Rate 4.5°C to 6.5°C (8°F to 12°F) per minute
- Control Heat Up 100°C to 150°C (210°F to 300°F)
- Vacuum 29 inches
- Cure in press 90 minutes at >182°C (360°F)
- Cool at <6° C/min (10°F/min)
- Lamination Pressure:

Panel Size		Pressure	
in.	mm	psi	kg/cm2
12 x 18	305 x 457	275	19
16 x 18	406 x 457	350	25
18 x 24	457 x 610	400	27

## CURING 55NT MULTILAYER BOARDS

Full cure of 55NT is necessary to achieve optimum material properties. The epoxy resin requires at least 90 minutes of cure above 182°C (360°F) to complete cross-linking of the resin matrix. Actual cure time may also be dependent on laminate thickness, number of laminates per book and the weight and distribution of copper layers or metal cores.

Note: It is suggested that designs for avoid use of 2 ounce copper power and ground planes if finished board CTE is an issue – large amounts of heavy copper will skew the CTE toward the value of pure copper which is 17 ppm/°C.

The cure of the multilayer board is typically evaluated by DSC. Once a process is established and tested for a given board design, cure results should be expected to be in the 150°C to 175°C range. When boards are properly cured, physical properties such as strength and toughness, chemical resistance and interlaminar strength will allow a more robust process window for board fabrication through drilling, routing and thermal excursions such as reflow and soldering.

## **DRILLING**

Because of the smoother laminate surface and softer fibers than E-glass, there is less drill wander with small drilled holes. This results in less breakout in annular ring pads. There is also less primary angle drill wear which may allow longer drill life.

We do NOT recommend the use of aluminum or aluminum-Clad entry or backup materials. Aluminum can become stuck on tip and cutting edges of the drill. The reinforcement is not as abrasive as glass and will not knock off the aluminum, leaving a drill point that will not cut cleanly.

Aramid fibers can block drill flutes when drilling small holes in thick boards or high stacks. Some of the following can be considered to reduce drill breakage: high strength carbide drills, reduced stack height, reduced drill withdrawal rate, peck drilling or high point angle drills.

A small orifice pressure foot is available on some types of drilling machines. An orifice of 3.5 mm (0.140") will keep the pressure on the entry material near the hole being drilled. This helps keep the material in solid contact with the board and reduces the chance of burrs and volcanoing. The pressure of the pressure foot should be at least 10 pounds. Do not allow the pressure foot to lift off of the stack, if possible, during the program. Any vibration will cause rough holes. Keep all debris out of the area between the entry and the board.

A drill template could also improve pressure applied near the hole. Drill a 1.6 mm piece of entry or FR-4 with slightly oversized holes; about 0.020 inch larger than the required final drill diameter.

The use of undercut drills are recommended for sizes less than 0.020 inch. These have increased flute volume for better evacuation of the debris and fibers.

Lubricated entry or backup materials are recommended to improve evacuation of the debris and fibers. This evacuation is key to improving hole wall quality.

The recommended backup material is a melamine coated phenolic/paper material. Other backup products with a hard surface that breaks up easily during drilling should work as well.

See attached Drill Table for starting drilling parameters. Testing should be done first as individual board design will affect results.

## **HOLE CLEANING**

For hole wall adhesion and etchback to have reliable interconnections, plasma offers the best plated through hole adhesion. Standard desmear and electroless operations can provide excellent copper adhesion and PTH reliability. Bake boards for 2 hours at 250°F to 275°F minimum to remove moisture and for improved consistency in plasma etchback. Avoid permanganate systems that use DMF or NMP as swell solvents as these may be absorbed and not readily surrendered by the aramid fibers. No glass etch is necessary as nonwoven aramid is a 100% organic reinforcement.

## **ELECTROPLATING**

Due to the constraint of CTE in the X-Y plane to 7-12 ppm/°C, in the finished PWB, the tradeoff in constrained core materials such as 55NT is that the Z-axis expansion will be higher than would be expected in a glass reinforced material. While experience is that the homogeneous nature of the distribution of the fibers in nonwoven aramid actually tends to increase PTH reliability (there being no fiber bundles intersecting hole walls to generate stress risers) the absolute CTE in the Z direction will be 90-120 ppm/°-C. Attention to plating baths should be directed at providing minimum elongation of 17-20% at 45,000 to 50,000 psi tensile strength. Plating to 1.5 mils (0.038 mm) will improve PTH reliability.

## **ROUTING / FABRICATION**

As previously mentioned, aramid fibers are softer than glass, so routing with a continuous cutting edge in a counter-clockwise profile provides a smoother finished edge. A 0.093 inch double fluted "end mill" type router is recommended at a speed of 30,000 rpm and a feed rate of 25 ipm. A rigid backing material such as phenolic or FR-4 placed on top of the panel stack with a good solid pressure foot will reduce fibrous edges. Do not use a brush type pressure foot, as this does not supply sufficient pressure to maintain intimate surface contact and eliminate vibration. Kraft paper placed against the board surface has also been demonstrated to reduce edge fuzz.

## **ASSEMBLY**

Due to the moisture absorption of aramid fibers and epoxy resin over time, it is important to remove moisture by baking boards prior to any thermal excursions that are part of assembly (reflow, etc), or thermal testing. Drying times and temperatures may need to be adjusted to account for the amount of copper cladding remaining on cap and innerlayer materials.

## **DESIGN CRITERIA**

Contact Arlon directly to discuss design recommendations to optimize performance of 55NT materials.

NOTE: The data provided herein is believed to be reliable but is provided for reference purposes only and is not intended to be process specific for any particular job. Determination of the suitability of any Arlon product for a specific end application is solely the responsibility of the purchaser. Arlon recommends careful engineering evaluation of any product before adopting in production PWBs, as the recommendations contained herein are starting points, and production conditions and/or circuit configurations may require process adjustments for optimization in either process yields or final board performance.
